

Patent Number: GB2119258

Title:

Endosseous dental implant system for overdenture retention, crown and bridge support

Abstracted Patent: US4431416

Inventor(s): NIZNICK GERALD A (US)

Applicant(s): A\_L INVESTMENT CO (US)

Application Number: US820372945 19820429

Priority Number(s): US820372945 19820429

IPC Classification:

**ABSTRACT:**

One part of the implant comprises a rigid screw anchor of substantially uniform diameter. The anchor has intermediate peripheral threads to engage the bone tissue at a prepared recess. The lower end of the anchor is hollow, peripherally perforated and open at the end to surround a bone core projecting from the bottom of the prepared recess. The upper end of the anchor has a relatively deep wrench socket for rotation of the anchor and for reception of a companion pillar part. The pillar part is made of slightly flexible plastic material that can approximate a prepared tooth to serve as a single tooth replacement or as a support for a fixed bridge. Optionally, the pillar can provide a platform that forms or mounts one of two companion elements of a connector structure such as for overdenture retention. The anchor can be altered in length not only at the bottom, but also at the top, without changing the manner in which the anchor cooperates with the later placed pillar.

(54) Dental implant

(57) One part of the implant comprises a rigid screw anchor (20) of substantially uniform diameter. The anchor has intermediate peripheral threads (40) to engage the bone tissue at a prepared recess. The lower end (36) of the anchor is hollow, peripherally perforated (52) and open at the end to surround a bone core projecting from the bottom of the prepared recess. The upper end of the anchor has a relatively deep wrench socket (44) for rotation of the anchor and for reception of a companion pillar part (22). The pillar part is made of slightly flexible plastic material that can approximate a prepared tooth to serve as a single tooth replacement or as a support for a fixed bridge. Optionally, the pillar can provide a platform that forms or

mounts one of two companion elements of a connector structure such as for overdenture retention. The anchor can be altered in length not only at the bottom, but also at the top, without changing the manner in which the anchor cooperates with the later placed pillar.

**SPECIFICATION****Endosseous dental implant system for overdenture retention, crown and bridge support**

5 This invention relates to dental implants and, particularly, to endosseous implants. 5  
Successful endosseous implants date from about 1968, at which time a biocompatible metal blade was fitted into a prepared elongated receptor site. The blade itself was perforated or vented to allow bone and blood vessels to reunite readily. A projecting metal head, either unitary with or detachable from the blade, provided an anchor for attachment of a fixed bridge.

10 Another endosseous metal implant design is the basket type having a projecting metal head. 10  
This implant is used specifically for partial support of a fixed bridge. Neither the blade nor the basket implant is designed or adapted for use as an anchor for over-dentures or use as a free-standing single tooth replacement to support a single crown. Solid root-shaped ceramic implants such as sold by Miter Co. of Worthington, Ohio, are used for support of a single tooth

15 replacement and for partial support of a fixed bridge, but are not adapted for use as an anchor 15  
for overdentures. Ceramic implants are stiff, brittle and bulky. They are not susceptible to specific case modifications.

The screw-type implants have been attempted for overdenture retention. The screw-type implant, such as sold by Zest Anchors, Inc. of San Diego, California, and Institut Shausman AG 20  
of Waldenburg, Switzerland, utilizes a solid self-tapping screw. 20  
A relatively small percentage of such sold screwtype implants have long term success. Commonly, failure occurs due to inadequate reattachment of bone tissue to the screw. Even in cases that appear to provide good connection, bone deterioration at the neck of the implant, as well as bone resorption at the threads, is often radiographically detected.

25 The basket type implant utilizes an inverted cylindrical cage or "basket" that fits about a 25  
cylindrical bone core and into an annular recess that is formed by an incomplete cut of a trephine drill. Perforations or vents in the basket or cage allow bone and blood vessels to reunite. A good mechanical fixation is accomplished, but only after a fairly lengthy healing period. Clearly, the screw-type implant is advantageous from the standpoint of immediate structural connection.

30 According to the present invention there is provided an endosseous implant anchor designed 30  
to be secured at a recess prepared in the cancellous bone tissue of a subject:  
(a) said anchor having an inverted core open at its lower end and peripherally perforated, said anchor core being adapted to encompass a bone core projecting upwardly from the bottom 35  
35 of the bone recess;  
(b) said anchor having a plurality of turns of screw threads adapted to engage the wall of said bone recess;  
(c) said anchor having a substantially cylindrical neck portion above said screw threads having a diameter not greater than the inside diameter of said screw screw threads and of a 40  
length sufficient to project just above the bone crest;  
(d) said anchor neck having means cooperable with a tool by the aid of which said anchor is threaded into said bone recess;  
(e) said anchor neck having an upwardly opening recess for placement of a companion part.

The present invention also includes an implant anchor designed to be secured within a recess 45  
45 prepared in the cancellous bone tissue of a subject, the anchor comprising an elongate body, a substantially cylindrical hollow portion at one end of the body and having a plurality of apertures formed therein, a substantially cylindrical neck portion at the other end of the body, a plurality of turns of screw thread about the body adapted to engage the wall of the bone recess, and means whereby the anchor may be threaded into the bone recess.

50 The implant system of present invention preferably provides: 50  
(1) a higher success rate as compared to the blade, screw and basket types of metal implants and compared to ceramic implants;  
(2) an anchor that is versatile enough to be used for the retention of an overdenture, the support of a fixed bridge, or the support of a crown for a single tooth replacement;

55 (3) an anchor that isolates the endosseous portion from the oral cavity during the healing state, and  
(4) an anchor that allows the actual head portion to become a part of the working laboratory model during construction of the fixed prosthesis capable of modification without annoyance to the patient prior to completion of the final prosthesis.

60 Another important feature of this invention is that the implant system may utilize a screw anchor so constructed that it can be precisely trimmed (1) to fit the specific jawbone recess; (2) to locate the screw threads at the required minimum distance beneath the bore crest; and (3) to locate the top of the anchor just slightly above the bone crest.

In a preferred form of this invention the endosseous implant is a two-part implant that 65  
65 includes as one part, a semi-rigid (or semi-flexible) pillar supported by the screw anchor adjacent

the level of the bone crest to maximise stability relative to lateral forces. Suitably the pillar may be a plastic pillar that has a flexural modulus of elasticity close to that of bone tissue itself and that can be trimmed, as need be, to change flexural characteristics closely to approximate the slight mobility found in natural teeth. Occlusal stresses are thus evenly transmitted to the bone.

5 Moreover, by providing a slight yielding or shock absorbing function, harmful stresses upon application of lateral occlusal forces are reduced. Avoidance of localized stress promotes an intimate and lasting contact between the bone and the metal screw anchor, not achieved by other implant systems.

Thus, in order to achieve the foregoing advantages the preferred implant comprises a

10 biocompatible implantable metal screw anchor that has an inverted perforated core at its lower end, a hollow wrench socket at its upper end, and self-tapping threads at the medial portion. The receptor site is prepared by drilling a cylindrical recess followed by drilling a deep annular kerf at the bottom of the recess, leaving a bone core. The available jawbone structure determines the size of the recess. The anchor is sized to the recess. Screw advancement seats

15 15 the core of the anchor about the bone core. The top of the anchor is located 1 mm above the crest of the bone, ultimately to be surrounded by gum tissue. The screw threads are located at least 1 mm below the crest of the bone. A chart assists the sizing operations.

The detachment and preparation of the companion pillar may be delayed to allow healing. In that event, a plastic rod of a matching diameter to the socket is inserted for later removal and

20 20 the gum tissue is sutured to close over the parts. Sooner or later the plastic pillar is installed in the socket. The plastic pillar can take a variety of forms, depending upon the requirements. It may simulate a tooth stump for a bridge; it may be prepared as a detachable connector for a denture; it may be crowned as a single tooth replacement. Flexural characteristics can be adjusted readily by slight physical alterations.

25 25 The invention will now be described by way of example with reference to the accompanying drawings in which like numerals designate corresponding parts in the several figures. These drawings, unless described as diagrammatic or unless otherwise indicated, are to scale.

Fig. 1 is a diagrammatic study corresponding to a commonly used radiographic development of the patient's lower jaw, showing two screw anchors implanted at the cuspid region of the

30 30 alveolar bone for overdenture retention.

Figure 2 is a diagrammatic vertical sectional view of a patient's mouth and illustrating in section, one of a pair of implants used to anchor the overlay denture.

Figure 3 is an enlarged axial sectional view of one of the implants in situ, part of the surrounding bone and gum tissue being shown in section.

35 35 Figure 4 is a perspective view of the metal screw anchor part of the implant.

Figure 5 is a diagrammatic view showing, by the aid of a plastic mouth model, the manner of connection of an overlay denture.

Figure 6 is an exploded view illustrating the preferred attachment structure together with a spacer.

40 40 Figure 7 is a perspective view of an unprepared plastic pillar that can support or be formed to provide one part of a two part connector.

Figure 8 is a perspective view of a modified screw anchor.

Figures 9 and 10 are sectional views similar to Fig. 3, showing two different commercially available attachments utilizing the pillar of Fig. 7.

45 45 Figure 11 discloses a third commercially available attachment anchored to the new implant.

Figure 12 discloses the implant used to support one end of a bridge, the implant including a pillar with a tapered head approximately the shape of a prepared tooth.

Figure 13 is a perspective view of the pillar of Fig. 12.

Figure 14 is a pictorial view of a special trephine drill for use in preparing the receptor site.

50 50 Figure 15 is an enlarged axial sectional view of the drill taken along a plane corresponding to line 15-15 of Fig. 14.

Figure 16 is an end elevational view of the drill taken in the direction of the plane 16-16 of Fig. 15.

Figure 17 diagrammatically illustrates the successive steps in the preparation of the receptor site and the placement of the implant.

55 55 Figures 18 and 19 are diagrammatic views similar to Figs. 17, but illustrating the procedures applied with less available jawbone.

Figure 20 is a drawing of a transparent chart used for determining proper configuration of the anchor.

60 60 Figure 21 is a drawing of a transparent chart used for determining proper configuration of the anchor.

The following detailed description discloses the best presently contemplated modes of carrying out the invention by way of example. Structural and operational characteristics attributed to forms of the invention first described shall also be attributed to forms later described, unless such characteristics are obviously inapplicable or unless specific exception is made.

In Fig. 1, two identical implants 10 are illustrated that are positioned at, or slightly inside the

65 65 cuspid region of the user's lower jaw to be well clear of the nerve canals 12. As shown by the

model in Fig. 5, each of the implants 10 carries one part 14 of a snap connector structure. The companion parts 16 are carried by the underside of an overlay denture 18.

Fig. 2 illustrates the implant position relative to the patient's mouth. The implant 10 (Fig. 3) comprises a generally cylindrical biocompatible metal screw anchor 20 and a plastic pillar 22.

5 The anchor 20 is installed in a recess prepared in the cancellous bone tissue 26. The recess comprises two parts. The upper part 28 is formed as a simple cylindrical hole of nominal diameter to a depth of seven or eight millimeters beneath the bone crest 30. The lower part 32 of the recess is a deep annular kerf or channel bounded on the inside by a bone core 34 and on the outside by a cylindrical surface of the same diameter as the upper recess part 28.

10 10 The anchor 20 fits the prepared recess. The lower part of the anchor 20 is in the form of an inverted hollow core 36 open at its lower end. The core 36 together with a central partition wall 38, caps the bone core 34. The intermediate portion of the anchor 20, just above the partition 38, is provided with three turns of self-tapping threads 40 that engage the wall of the upper recess part 28. The threads 40 immediately provide a firm connection to the jawbone. The 15 outside diameter of the core 36 equals the inside diameter of the threaded portion.

15 The upper neck end of the anchor 20 is cylindrical and has a diameter about equal to the inside diameter of the threads 40. The neck projects slightly as, for example, about one millimeter above the bone crest 30 so that the gum tissue 42 can readily cap it. In order to rotate the anchor 20 into position, a wrench (not shown) fits a relatively deep hexagonal socket 20 20 44 (see also Fig. 4) at the top of the anchor 20. The socket 44 extends to the partition 38. The major diameter of the socket may be about three and one-quarter millimeters. If the neck of the anchor is trimmed for the purposes to be explained more fully hereinafter, the socket 44, deeper as it is, remains functional.

20 The anchor 20 is sized to fit the available jawbone as determined in advance by a method 25 herein described. By this method, the threads will be placed at least one millimeter below the bone crest and preferably more, so that the thread channels are not conduits or receptacles for contaminants. One of two standard anchors is selected—one of larger diameter, say 5.5 millimeters and the other say 4.5 millimeters. Both have an overall length of 16 millimeters with a 5.5 millimeter neck, 3.5 millimeters of threads, and 7.5 millimeters of core. If a jawbone of 30 30 quite ample depth is to be fitted, a trephine drill 48 cuts a circular channel to a depth corresponding to the sum of the lengths of the threads and the neck, less one millimeter for projection above the bone. Thus, at A in Fig. 17, the upper recess part 28 is drilled to a depth of 7.5 millimeters, leaving the bone core 50, as at B. The core 50 is carefully broken off by a tool 52, as at C. The bottom of the recess 28 is levelled off by scraping, as at D. The lower 35 35 recess part 32 is now prepared to a depth of 7.5 millimeters, as at E, leaving the bone core 34 in place, as at F. The anchor 20 can now be installed, as at G.

In the example of Fig. 18, the jawbone is less ample and the maximum recess depth of 13 millimeters is determined. The neck is simply shortened two millimeters to 5.5 millimeters, and the upper recess part correspondingly formed to that depth, as indicated at A, B, C and D in 40 40 Fig. 18. The lower recess part 32 is formed to the maximum depth as in the previous example. The threads 40 are located an adequate distance beneath the crest 30.

In the example of Fig. 19, the maximum recess depth is 9.5 millimeters. The core is 45 45 shortened 2.5 millimeters and the neck is shortened 3 millimeters. Circular gauge markings on the neck of the anchor 20, as well as a circular gauge marker on the core 36, facilitate trimming before surgery. Circular gauge markings on the drill assist in accurately sizing the recess.

The advance study to determine the anchor size begins with a panoramic x-ray which typically magnifies about ten percent (10%). A transparency depicting six modifications of an anchor is provided on a corresponding scale so that by juxtaposition of the two, a suitable anchor configuration can be selected. A drawing of such a transparency is shown in Fig. 20.

50 50 The following chart indicates the required modifications of the standard anchor in order to obtain the selected modification:

MODIFI- 5 CATION#	AVAILABLE BONE	SHORTEN NECK	REMOVE ONE ROW OF VENTS	PREPARE IMPLANT SITE WITH 7-1/2 mm CORE DRILL	5

20					20

While the self-tapping screw threads 40 provide an immediate mechanical connection to the jawbone, the mechanical connection is completed in a positive manner by growth or regrowth of bone tissue. For this purpose, the anchore core 36 has three rows of perforations 52 about its entire area (see Figs. 3 and 4). Bone and blood tissues on the inside and outside of the core 36 will link up through the holes 52. The thickness of the core wall being small, bridging of blood vessels and bone tissue will begin in a relatively short time. Mechanical connection is furthermore provided by the intimate adaptation of the walls of the prepared bone cavity and the outer surface of the anchor, both being of equal diameter.

The first or uppermost turn of the threads 40 forms a stop to isolate the lower regions of the anchor 20 from infiltration of foreign matter. By the time, if ever, that resorption occurs at the region of the threads 40, bone tissue will have grown about the anchor neck and through the perforations 52 at the core 36, ensuring a lasting, well anchored implant.

35 In Fig. 8, there is illustrated an anchor 100 that is similar to the anchor 20 shown in the form of Fig. 4, except that the screw thread portion 102 of the anchor 100 is moved to the lower core region. Perforations 104 are formed through the screw thread portion. This thread arrangement allows the anchor to be accommodated in a very small receptor site.

The receptor site may be closed to allow a healing period of some number of weeks before a 40 pillar 22 (Fig. 3) of proper size is cemented to the socket 44. The pillar 22 is sized to fit the depth of the socket 44 as by the aid of gauge marks 53.

My preferred attachment comprises a ball 54 (see also Fig. 6) and snap socket 56. The socket 45 is formed at the head or platform 58 of the pillar 22. The pillar 22 provides a neck 60 just above the top of the anchor 20 (Fig. 3) and about which the gum tissue can grow. The head 58 of the pillar 22 projects only about 3 millimeters above the gum tissue so that the lateral force exerted by the ball 54 on the socket 56 acts over a very short lever arm. The small torque is effectively resisted by the anchor.

The ball 54 is formed at the lower end of a connector 62. The connector is attached to a downwardly opening recess 64 of the denture 18. The denture recess 64 surrounds the pillar 50 head 58 with ample clearance. The socket 56 has a restricted opening 66 that engages a neck 68 at the base of the ball 54. The depth of the socket 56 provides one-half a millimeter of clearance relative to the ball when the denture is in place. This ensures that the bit force is transmitted via the denture to the gum tissue 42, bypassing the implant in the transmission of such force. Yet, the socket 56, together with the socket of the companion implant, provide the 55 requisite lateral stability and retention.

The connector 62 in the present instance has a series of annular ribs 70 for locking to the denture structure. The connector 62 may be made of plastic such as CELCON® brand acetal copolymer of the Celanese Corporation.

The impression of the lower jaw is made with the preferred socketed pillar (Fig. 6) placed in 60 the socket 44 of the anchor 20. A spacer 72 is placed on top of the pillar so that as the impression is made, the ball 54 is at its nominal position at the top of the socket. By the aid of the impression, and in a well understood manner, the lower denture is made with the connectors 62 accurately located.

The material of which the pillar 22 is made has suitable density, resilience and flexibility. 65 CELCON has a flexural modulus that closely approaches that of normal bone tissue. The

flexibility of the pillar may be made more or less, depending upon the nature of the particular case. For example, if the depth of the implant is necessarily restricted, or if the bone tissue is weak, then flexibility can be added to the pillar in order to minimize the load by increasing the height of the head or reducing the neck 60.

5 The acetal copolymer ball 54 and the pillar 22 interact in a manner to dissipate the forces under occlusal function. The flexibility is achieved apart from the metal anchor 20, which is itself rigid and which is rigidly affixed to the jawbone. The pillar can be prepared for other attachments. 5

Thus, the unprepared pillar 74 shown in Fig. 7 provides a head 76 ready for adaptation. Figs. 10 9 and 10, respectively, illustrate pillars prepared to serve as attachments sold under the trademarks or trade names SCODENCO and ZEST. In Fig. 9, a male connector part is secured to the pillar. In Fig. 10, a female connector part is secured to the pillar. UDEL® brand polysulfone sold by Union Carbide Corporation is quite suitable for the connectors of Figs. 9 and 10, since this material provides good bonding and cutting characteristics. Fig. 11 illustrates a model with 15 a bar 80 secured to two of my implants. The bar 80 cooperates with two clips 82 of the denture. One bar attachment of this configuration is known as the PRECIHORIX. 15

A slightly modified pillar can be used in the same manner as a prepared tooth for supporting a crown or a bridge. Thus, Fig. 12 illustrates a bridge 90 anchored at one end by a prepared natural first bicuspis 92, and at the other end, by a pillar 94. The pillar 94, in this instance, has 20 a frusto-conical head 96 (see also Fig. 13) that corresponds to the prepared tooth. The pillar 94 is secured to the previously described screw anchor 20. Gauge marks 98 on the pillar 94 (Fig. 13) facilitate requisite trimming. The pillar 94 obviously can be used to support a crown or other prostheses. 20

The drill 120 shown in Figs. 14, 15 and 16, has an inverted cylindrical cup 122 with teeth 25 123 at its lower end. The shank 124 of the drill 120 connects to a latch-type slow speed contra angle hand piece (not shown). The shank has a through passage 126 to allow movement of a cooling fluid. Both the cup 122 and the shank 124 have circular markings 128 and 130 so that the depth of cut can be gauged. The part of the cup below the markings 128 is provided with peripheral ridges 132 that slant upwardly to guide material outwardly. Fluid that enters the drill 30 cup via passage 126 may move out through holes 127 in the cup 122. Some fluid may move downwardly to the teeth 123, and then outwardly and upwardly along the flow channels formed by the ridges 132. 30

The interior diameter of the cup recess 134 increases from a minimum at the teeth 123 so that good running clearance is provided as the bone core is formed. The exterior surface of the 35 cup 122 is reduced at the upper region to provide good running clearance with the jawbone recess being formed. 35

#### CLAIMS

1. An endosseous implant anchor designed to be secured at a recess prepared in the cancellous bone tissue of a subject: 40
  - (a) said anchor having an inverted core open at its lower end and peripherally perforated, said anchor core being adapted to encompass a bone core projecting upwardly from the bottom of the bone recess;
  - (b) said anchor having a plurality of turns of screw threads adapted to engage the wall of 45 said bone recess;
  - (c) said anchor having a substantially cylindrical neck portion above said screw threads having a diameter not greater than the inside diameter of said screw threads and of a length sufficient to project just above the bone crest;
  - (d) said anchor neck having means cooperable with a tool by the aid of which said anchor is 50 threaded into said bone recess;
  - (e) said anchor neck having an upwardly opening recess for placement of a companion part.
2. The endosseous implant as set forth in claim 1 together with a pillar fitted to said anchor recess to form or to support a dental restoration or the like.
3. The endosseous implant as set forth in claims 1 or 2 in which said anchor recess is non-circular to comprise said tool cooperable means. 55
4. The endosseous implant as set forth in any of the preceding claims in which said anchor has gauge marks by the aid of which said anchor is fitted to the bone recess of the subject.
5. The endosseous implant as set forth in any of the preceding claims in which said threads are formed just above said inverted core. 60
6. The endosseous implant as set forth in any of claims 1 to 4 in which said threads are located at said inverted core, said perforations extending between said threads.
7. The endosseous implant as set forth in any of the preceding claims in which said pillar is made of semi-rigid plastic material having both resilience and limited flexibility, said pillar having a neck at the region just above the top of said anchor to provide controlled lateral 65 flexibility. 65

8. The endosseous implant as set forth in claim 7 in which said pillar provides a platform with a snap-in ball socket having a restricted opening to form said one of two companion connector structures; and a denture fitted to the subject's gum and having a ball entering said socket to stabilize said denture, said socket providing an extended stress-free space beneath the ball when the denture is in its nominal position. 5

9. The endosseous implant as set forth in any of claims 2 to 6 in which said pillar provides a frustoconical head simulating or approximating a tooth prepared for a dental prosthesis.

10. The endosseous implant as set forth in claim 9 in which said pillar is made of plastic material to simulate the mobility of natural teeth.

10 11. An implant anchor designed to be secured within a recess prepared in the cancellous bone tissue of a subject, the anchor comprising an elongate body, a substantially cylindrical hollow portion at one end of the body and having a plurality of apertures formed therein, a substantially cylindrical neck portion at the other end of the body, a plurality of turns of screw thread about the body adapted to engage the wall of the bone recess, and means whereby the 15 anchor may be threaded into the bone recess.

12. An implant anchor designed to be secured within a recess prepared in the cancellous bone tissue of a subject substantially as hereinbefore described with reference to and as illustrated in the accompanying drawings. 15
